Analysis of the Code and Control Strategy

Sensor Logic and Decision Making

This code employs a simple if-else logic based on sensor inputs:

- Both sensors detecting the line prompts the robot to move forward.
- Only the left sensor detects the line, indicating the robot has veered right; hence, turn left.
- Only the right sensor detects the line, indicating the robot has veered left; hence, turn right.
- If no sensors detect the line, the robot stops or could implement a search maneuver.

Control Strategy Effectiveness

While this approach is straightforward, it has limitations:

- Sharp Turns: Not smooth; sudden changes can cause instability.
- Line Loss: No search pattern if the line is lost.
- Sensor Noise: May cause jitter or oscillations.

To improve precision, implementing PWM-based motor control and PID algorithms is advisable.

Implementing PWM for Motor Speed Control

Using PWM signals can smooth out turns and provide better control. For Atmega8, this involves configuring timers and output compare registers.

```c

// Example: Initialize Timer1 for Fast PWM

void pwm_init() {

// Set OC1A and OC1B pins as output

DDRD |= (1
// Configure timer

TCCR1 |= (1
}
```

```

PID Control Algorithm

A PID controller adjusts motor speeds based on proportional, integral, and derivative components, which reduces oscillations and improves line tracking accuracy. Implementing PID involves:

- Reading sensor inputs
- Calculating error (deviation from center)
- Computing PID output
- Adjusting PWM duty cycles accordingly

Sensor Array Expansion

Adding more sensors (e.g., 5 or 8 reflectance sensors) enhances line detection fidelity, allowing for more precise control algorithms like center-of-line or edge following.

Challenges and Troubleshooting

- Sensor Calibration: IR sensors may require calibration for ambient light conditions.
